following the claims:

5   --<u>Abstract</u>

The method is for sending messages over secure communication
links in networks with a mobile terminal and at least one
other terminal. A secure communication link is established
between a given initial network address of the mobile terminal
10 and the address of the other terminal. The secure
communication link defines at least the addresses of the two
terminals. The secure communication link supports an
encapsulation method to overcome network address translations
and/or other translations. When the mobile terminal moves
15 from an initial network address to a new network address, a
request message is sent from the mobile terminal to the other
terminal to change the secure connection to be between the new
address of the mobile terminal and the other terminal. The
request is sent using said method to overcome network
20 translations. The other terminal responds to the mobile
terminal with a reply message with a description about the
overcoming methods supported by the other terminal. All
messages are thereafter sent from the mobile terminal to the
other terminal by using the information sent with said reply.--
